Background

- Next-generation sequencing (NGS) is increasingly available in lowresource settings.¹
- Potential applications of NGS include pathogen detection for disease mapping, which can inform diagnostic algorithms and identify emerging pathogens.²

Objectives

Use metagenomic NGS to characterize the respiratory disease landscape in Cambodia.

Methods

Study participants: From December 2020, individuals aged 2 months to 65 years presenting to 4 tertiary hospitals in Cambodia with fever and respiratory symptoms were prospectively enrolled.

Sample processing: Nasopharyngeal (NP) swabs were obtained within 24 hours of documented fever. Paired serum samples were obtained for the first 6 months of the study. Total nucleic acids were extracted from biospecimens and metagenomic RNA libraries prepared and sequenced on a NextSeq2000 instrument.

Analysis: Raw sequence reads were stripped for host reads and aligned to NCBI nucleotide and protein databases using a cloudbased bioinformatics platform.

Ethics and protocol registration and Ethics: The study protocol was approved by NIH and Cambodian IRB and the trial prospectively registered on clinicaltrials.gov (NCT04034264).

Study Cohort

Table 1. Cohort characteristics.

Characteristic	Total N= 436
Male gender, N (%)	248 (57%)
Age in years, Median (IQR)	2 (1-7)
Urban location	261 (60%)
Symptom, N (%)	
Cough	357 (82%)
Rhinorrhea	303 (69%)
Dyspnea	132 (30%)
Symptom duration, N (%)	
<= 1 day	175 (40%)
2-4 days	196 (45%)
>= 5 days	65 (15%)
Pathogen hit, N (%)	238 (55%)

Results

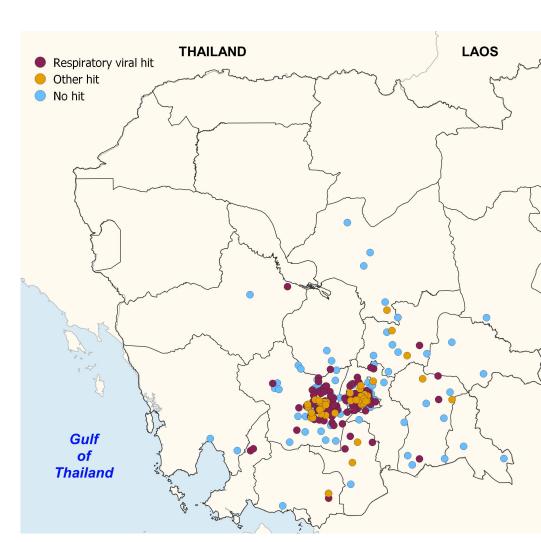

Fig 1. Map of Cambodia with geolocation of sampled cases. Purple= respiratory virus, orange= other pathogen, blue= no pathogen.

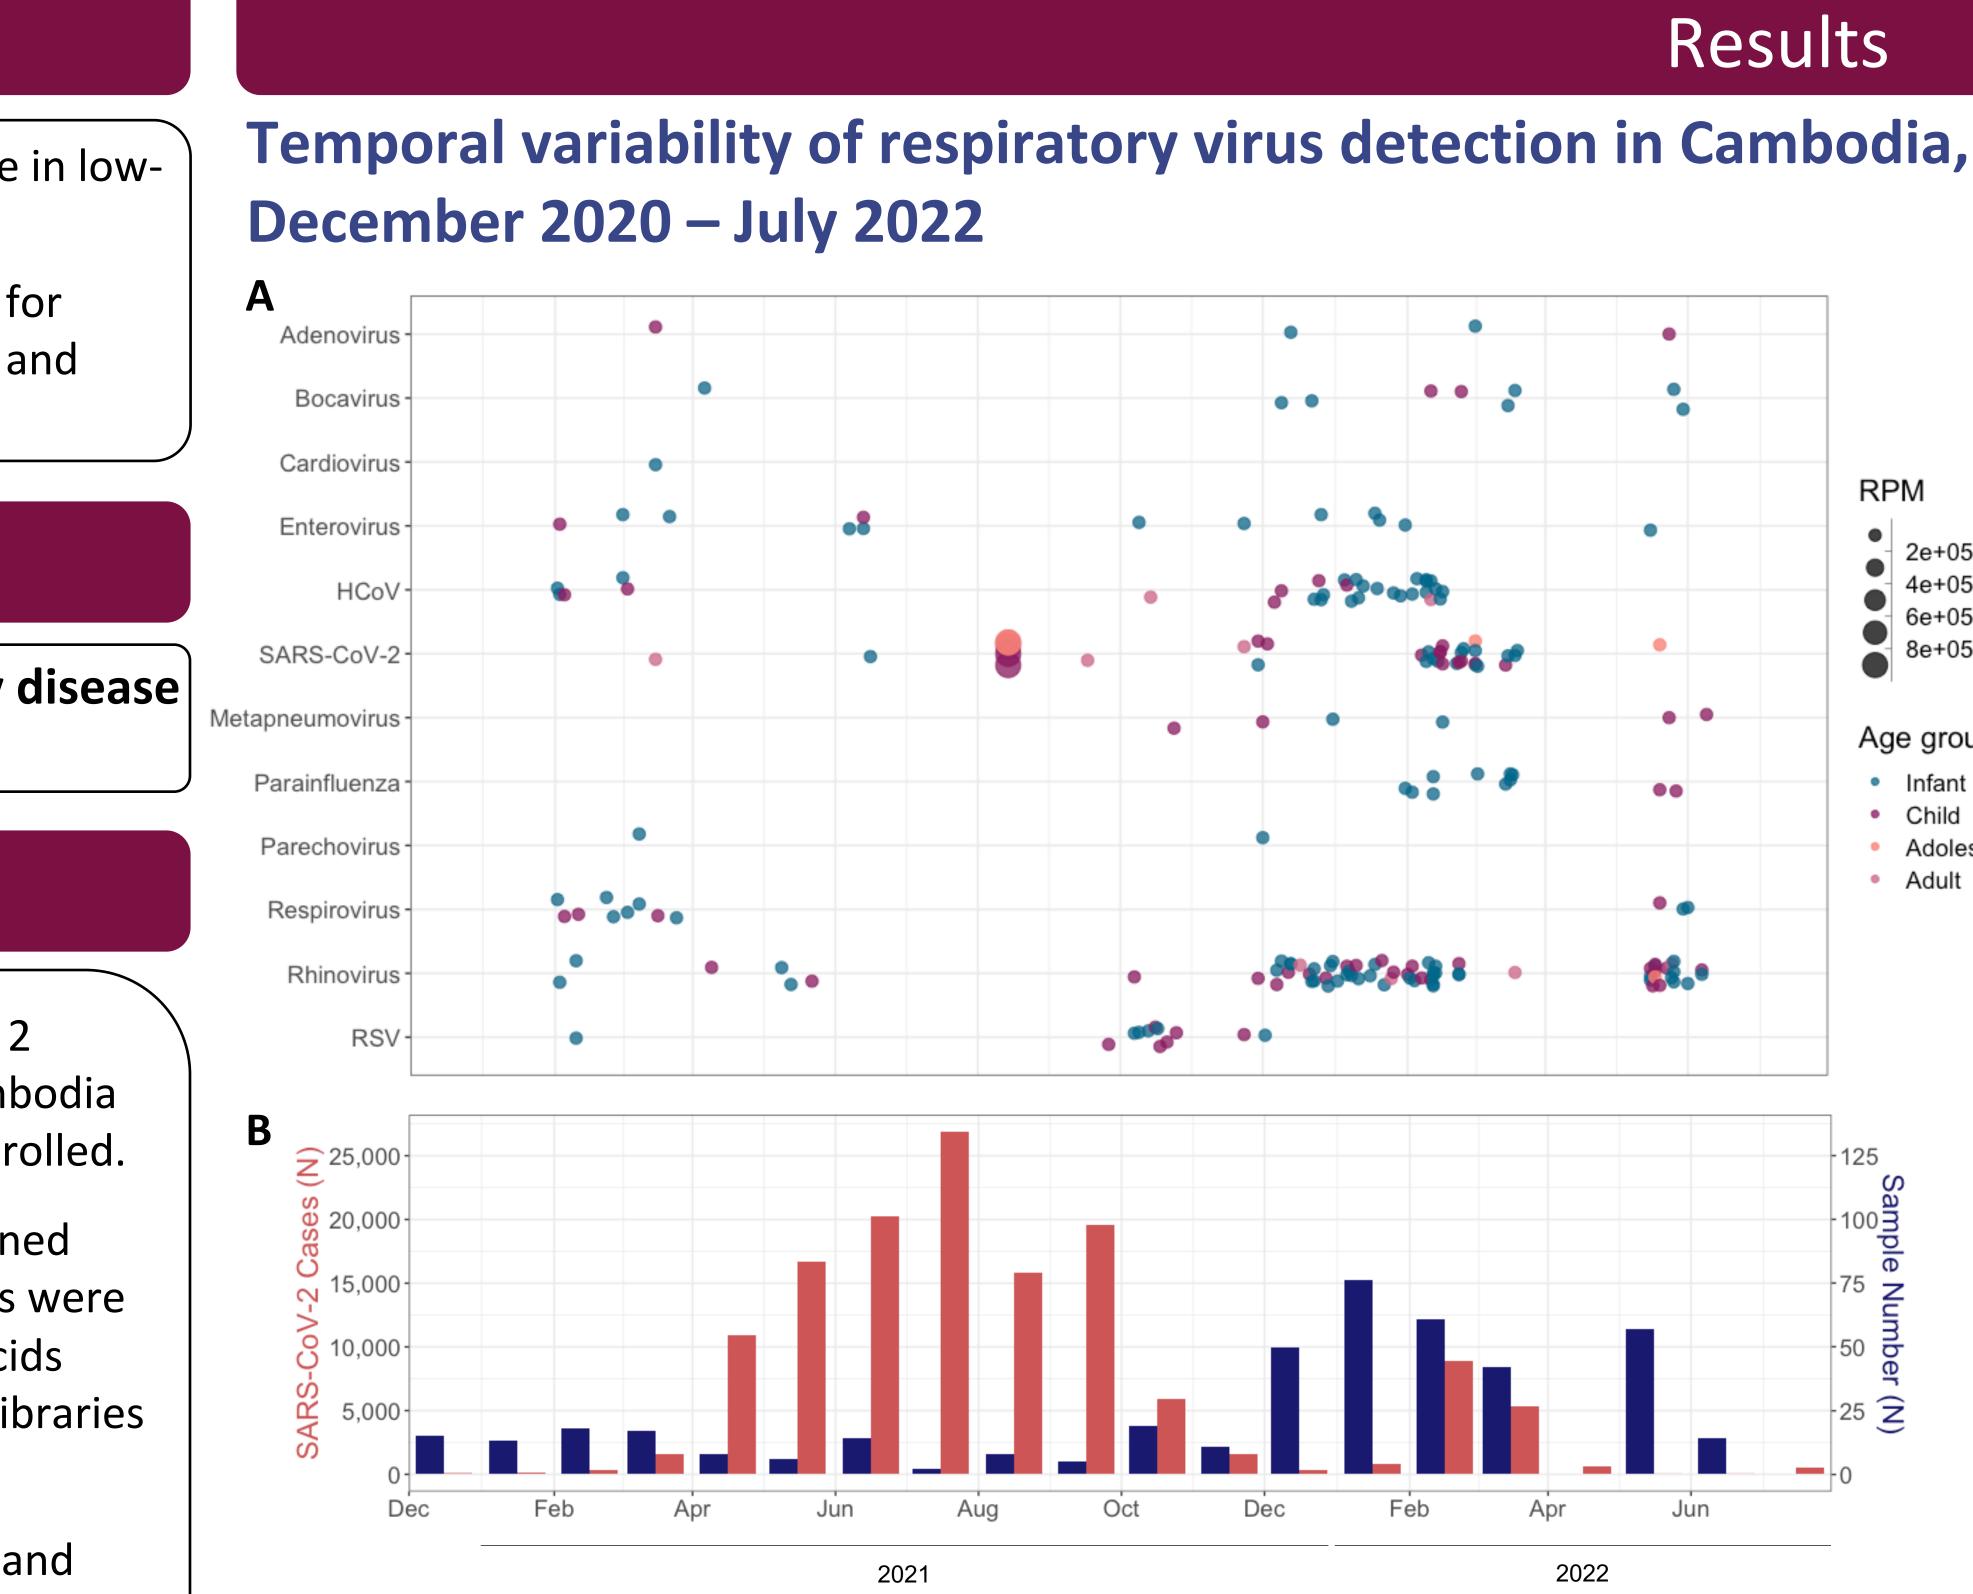

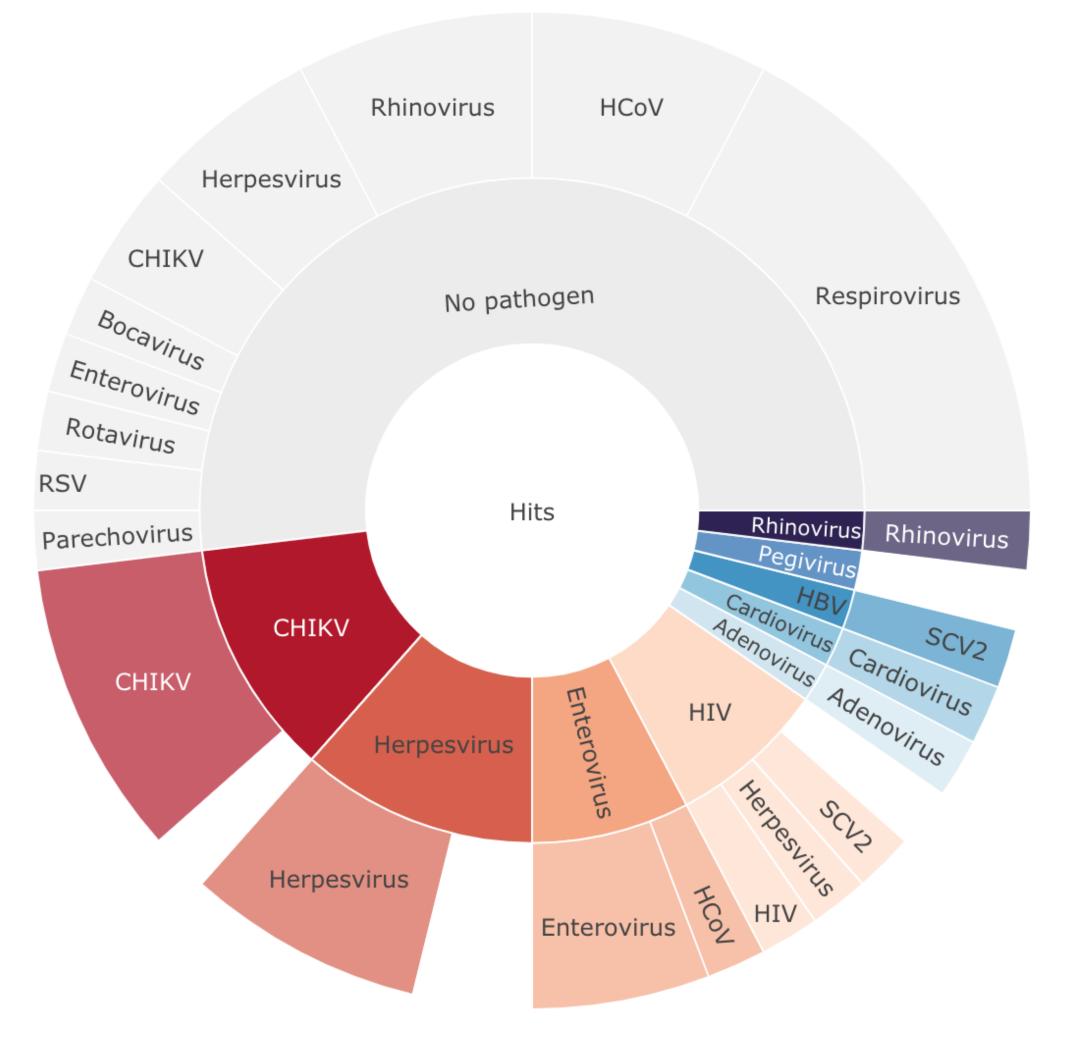

Fig 2. (A) Dot plot of respiratory viruses in NP swabs of febrile individuals. (B) Monthly new SARS-CoV-2 cases in Cambodia (red) and study samples (blue). HCoV = Human (non-SARS-associated) coronaviruses; RSV = Respiratory syncytial virus.

Detection of systemic viruses in nasopharyngeal swabs

Fig 3. Sunburst plot of pathogen hits in paired serum and NP samples for individuals with any pathogen identified. Inner and outer circles represent sera and NP hits, respectively. CHIKV = Chikungunya virus; HBV = Hepatitis B virus; SCV2 = SARS-CoV-2; HIV = Human immunodeficiency virus.

- Pathogens were detected in NP swabs of 27 cases without hits in sera.
- CHIKV was detected in NP swabs in 5 of 6 individuals and HIV in 1 of 4 individuals with corresponding pathogen detection in sera.

Results

Composition of nasopharyngeal microbiome by presence of respiratory viruses Microbial diversity was reduced in samples containing respiratory viral pathogens. RPM Relative abundance of *Streptococcus* 2e+05 spp was increased while that of 4e+05 6e+05 Corynebacterium, Pseudomonas, 8e+05 Acinetobacter, and Malassezia spp Age group were decreased in samples with Infant respiratory viruses. Child Adolescent No hit Adult Genus: Corynebacterium Genus: Pseudomonas Genus: Acinetobact Genus: Malasseziaceae 0.75 ღ 0.25-No hit Hit Genus: Dolosigranulum Genus: Moraxella Genus: Streptococcus Fig 4. Simpson's ns ns index (A) and 0.75 abundance of top taxa **(B)** by 0.5Dec Feb Apr

No hit

Hit

0.25

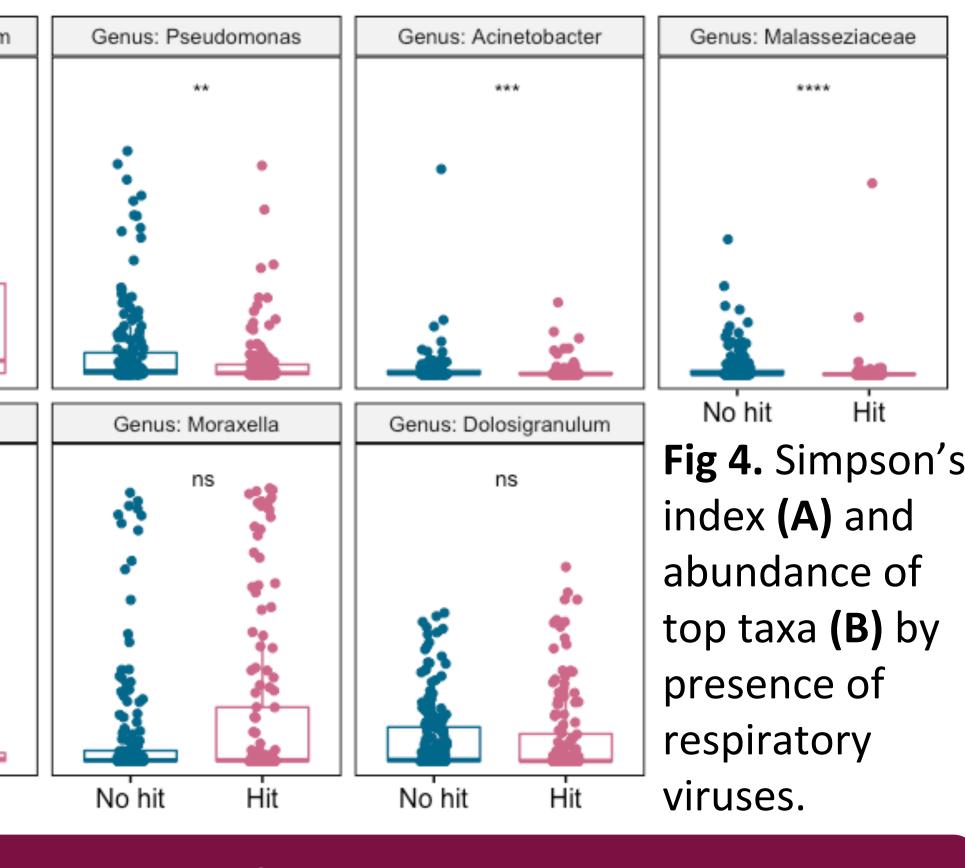

- present in sera.
- in nasopharyngeal samples.

Conclusions

Metagenomic NGS can be successfully implemented in lowresource settings to identify common and emerging pathogens.

Nasopharyngeal sampling may reveal potential pathogens not

Certain viral pathogens causing systemic disease, even if not classically associated with respiratory disease, may be detected

The composition of the nasopharyngeal microbiome varies with presence/absence of respiratory viruses.
