Background

Health care personnel (HCP) are at increased risk for SARS-CoV-2 exposure. However, the exposure sources among HCP are poorly understood.

Objectives

We describe burden of SARS- CoV-2 infection among HCPs in a large healthcare facility, sources of infection and occupational factors such as role, setting, vaccination status and patient contact.

Methods

- Design: We conducted active prospective surveillance for all employed HCP newly diagnosed with COVID-19 between March 2020 and May 2022.
- Setting: SUNY Upstate Medical University
- Data collection: We inquired about their sources of exposure using a standardized health department checklist and CDC guidance for managing healthcare personnel with SARS-CoV-2 infection or exposure.
- Data Analysis:
 - Frequencies and percentages of employment characteristics, masked contact, and vaccination status were described across COVID-19 exposure categories and statistically compared with chi-square statistics.
 - Cumulative incidences of COVID-19 were calculated for all cases and separately among each exposure type.

Results

- We identified n=4,430 HCP COVID-19 cases between March 2020 and May 2022.
- The median age of cases was 37 years (range 18-89); 2840 (64.1%) were females; and the majority were white (n=2907, 65.6%).
- Most of the infected HCP were in the general medicine department followed by ancillary departments, and support staff. Less than 10% of HCP positive cases worked on a COVID unit, only 194 (4.4%) admitted unmasked contact with a patient or co-worker.

Source of Exposure

• Most of the reported SARS-CoV-2 exposures were from an unknown source n=2,571 (58.0%), followed by household source, n=1,185 (26.8%), community source n=458 (10.3%) and health care exposures, n=211 (4.8%).

Ch

Results (cont.)

Vaccination Status

• A higher proportion of cases with reported health care exposures were vaccinated with only 1 or 2 doses, while a higher proportion of cases with reported household exposure were fully vaccinated and boosted (p<0.0001), table 1.

	Health Care	Household Exposure	Community Exposure	Unknown Exposure
aracterístic	Exposure (N=211)	(N=1185)	(N=458)	(N=2571)
	No. (%)	No. (%)	No. (%)	No. (%)
vid Vaccine Doses				
Doses	58 (27.5)	321 (27.1)	174 (38.0)	991 (38.6)
or 2 Doses	90 (42.7)	396 (33.4)	154 (33.6)	784 (30.5)
Doses	63 (29.9)	468 (39.5)	130 (28.4)	796 (31.0)

*Five cases (0.1%) were missing information on exposure type.

Hospital Role

• The cumulative incidence of COVID-19 among the 8,766 HCP employees during the study period was 35.2%. There was statistically significant variability in incidence by hospital role (p<0.0001), with registered nurses being the most likely to be infected (n=888, 47.9%), followed by Master's level clinicians (n=84, 39.6%). Administration and management were the least likely to be infected with COVID-19 (n=173, 21.4%).

• Registered nurses with unknown source of exposure, had the highest incidence of 26.4%.

• Statistically significant variability was also found by level of patient contact (p<0.0001), with increasing level of patient contact resulting in increasing incidence of COVID-19.

COVID-19 infection among HCP and community level transmission

• HCP exposure to COVID-19 correlated with community level transmission regardless of type of reported exposure, figure 1.

• The sources of exposure have not changed substantially over time, figure 2.

Figure 1. HCP COVID-19 cases by source of exposure (Left Axis) in the Central New York region (Right Axis) between March 2020 and May 2022.

Golisano Children's Hospital

Conclusions

 Interpretation of the product of the p by household and community exposures.

- Health care setting was not an important source of infection among HCP and was reported in less than 5% of HCP.
- We have observed substantial variability of SARS-CoV-2 infection incidence among HCP with different hospital roles.
- COVID-19 infections among HCP correlated closely with community level.
- HCP are aware of occupational risks. HCP may let down their guard in nonoccupational settings where exposure risk, although less obvious, may in fact be greater.

Next steps

- We must remain diligent and educate HCP about community risk to address transmission through all source settings.
- It is unclear what specific factors contributed to elevated risk among nurses and should be a focus of future study.
