INTRODUCTION

Taniborbactam is a novel cyclic boronate-based broadspectrum β -lactamase inhibitor with selective direct inhibitory activity against both serine- and metallo- β lactamases. Taniborbactam restores the activity of cefepime against many difficult to treat organisms, including cephalosporin- and carbapenem-resistant Enterobacterales and *Pseudomonas aeruginosa*. Antimicrobial resistance is typically higher in isolates collected from ICUs, leaving clinicians with limited treatment options. In this study, we evaluated the *in vitro* activity of cefepime-taniborbactam and comparator agents against clinical isolates of Enterobacterales and P. aeruginosa collected from ICUs and non-ICUs in a 2018-2020 global surveillance study.

METHODS

MICs of cefepime with taniborbactam fixed at 4 mg/L (FTB) and comparators were determined using the CLSI reference method [1] against Enterobacterales (n=12,428) and P. aeruginosa (n=4,314) collected in 2018-2020. Quality control (QC) testing was performed each day of testing as specified by the CLSI [1, 2]. Isolates were collected from community and hospital infections from 266 sites in 56 countries. Only isolates collected from patients in wards designated ICU (n= 5,225 Enterobacterales/1,947 P. aeruginosa) and non-ICU (n= 7,243 Enterobacterales/2,367 P. aeruginosa) were included in this analysis. Isolates were sourced from (n/percent of total): respiratory tract infections (6,911/41.3%), urinary tract infections (3,245/ 19.4%), intraabdominal infections (2,537/15.2%), bloodstream infections (2,431/14.5%), skin/soft tissue infections (1,616/9.7%), and unknown (2/<0.1%). Avibactam was tested at a fixed concentration of 4 mg/L in combination with ceftazidime, tazobactam was tested at a fixed concentration of 4 mg/L in combination with ceftolozane and piperacillin, and vaborbactam was tested at a fixed concentration of 8 mg/L in combination with meropenem. Resistant phenotypes were based on 2022 CLSI breakpoints [2]. Multidrug resistant (MDR) was defined as resistance to at least one agent from ≥ 3 drug classes based on CLSI 2022 breakpoints [2]. As there is no CLSI breakpoint for meropenem-vaborbactam for P. aeruginosa, the EUCAST 2022 susceptible breakpoint of ≤8 mg/L has been applied [3]. As cefepimetaniborbactam breakpoints have not yet been established, the provisional susceptible (S) breakpoint of ≤16 mg/L was applied for cefepime-taniborbactam for comparative purposes.

RESULTS SUMMARY

- Cefepime-taniborbactam showed in vitro activity against Enterobacterales, with MIC_{90} values of 0.25 mg/L for isolates from non-ICU patients and 0.5 μ g/mL for isolates from ICU patients (Table 1, Figure 1). Greater than 99% of all Enterobacterales from both wards were inhibited by $\leq 16 \text{ mg/L}$ of cefepime-taniborbactam.
- Cefepime-taniborbactam maintained activity against resistant phenotypes of Enterobacterales in both ward types, with 94.8 -99.8% of isolates inhibited at $\leq 16 \text{ mg/L}$.
- The percent susceptible to comparator agents against the resistant subsets ranged from 1.6% to 92.6% for Enterobacterales (Table 1, Figure 3).
- Cefepime-taniborbactam showed in vitro activity against P. *aeruginosa*, with an MIC₉₀ value of 8 mg/L and inhibiting at least 96.9% of isolates at ≤ 16 mg/L for both ICU and non-ICU isolates (Table 2, Figure 2).
- Cefepime-taniborbactam maintained activity against resistant phenotypes of *P. aeruginosa* in both ward types, with 84.7% to 92.5% inhibited at $\leq 16 \text{ mg/L}$ (Table 2).
- The percent susceptible to comparator agents against the resistant subsets of P. aeruginosa ranged from 35.2% to 68.4% (Table 2, Figure 4).
- Against the particularly challenging subset of MDR P. aeruginosa from ICU patients, cefepime-taniborbactam was the most active agent tested as it inhibited 84.7% of isolates at ≤ 16 mg/L compared to 43.1% susceptible to ceftazidime-avibactam, susceptible to ceftolozane-tazobactam, 35.2% 36.0% susceptible to meropenem-vaborbactam.

CONCLUSIONS

- Cefepime-taniborbactam demonstrated potent in vitro activity against Enterobacterales and P. aeruginosa from ICU and non-ICU wards, including difficult to treat resistant subsets of isolates.
- This supports the continued development of cefepimetaniborbactam as a potential new treatment option for infections due to resistant Gram-negative pathogens.
