1817 Presentation: 19-23 Oct 2022

Background

- Staphylococcus lugdunensis (S. lugdunensis) belongs to a group of coagulase negative Staphylococci (CoNS), which is present as a normal skin commensal in healthy individuals.
- Invasive infections caused by S. lugdunensis has been increasingly reported ¹⁻⁵.
- Whereas, there is no treatment guideline for *S. lugdunensis* bacteremia (SLB) due to a little clinical data.
- Owing to assess appropriate management for SLB, we conducted a retrospective case-control study to investigate characteristics, clinical courses and outcomes for SLB compared with those of Staphylococcus aureus (S. aureus) bacteremia and bacteremia due to Staphylococcus epidermidis (S. epidermidis), which is most common pathogen in CoNS-related bacteremia.

Materials and Methods

- **Setting, study design:** This retrospective case-control study was conducted at Kyoto University Hospital, a tertiary care 1141bed university hospital located in Japan, from January 1, 2005 to December 31, 2021.
- **Patients:** Patients who had at least one set of blood culture collection were included in this study. Of those, patients >=18 years of age with SLB with at least two sets of positive blood cultures, those who had S. aureus bacteremia (SAB) with at least one set of positive blood culture and those who had S. epidermidis bacteremia (SEB) with at least two sets of positive blood cultures were randomly selected in a 1:5:5 (SLB:SAB:SEB) ratio.
- Variables: Patients characteristics, illness severity, source of bacteremia, metastatic lesions, clinical managements (follow-up blood culture, echocardiography, early source control, days to appropriate treatment, early optimal therapy and duration of treatment) and outcomes were reviewed.
- **Statistical analysis:** When a p-value of <0.05 was revealed for comparisons among three groups, followed comparisons between SLB and SAB, and between SLB and SEB were performed.

- Intravascular catheter related bloodstream infection was the most common in each group as source of bacteremia except for unknown focus.
- The proportion of metastatic lesions was comparable between SLB and SAB, higher in SLB than in SEB.

- patients with SLB.

Department of Clinical Laboratory Medicine, Kyoto University Graduate School of Medicine yukawa@kuhp.kyoto-u.ac.jp +81+75-751-3502

SLB is associated with complicated infections and high mortality. Echocardiography was performed less frequently in SLB than in SAB. Clinical outcome for SLB was worse, as same as that of SAB. Appropriate evaluation and treatment that are recommended for SAB maybe warrant for
