### Background

Pregnancy is one of the risk factors associated with the severity of Coronavirus Disease 2019 (COVID-19). The perinatal complications also known to be increased when pregnant women become infected with COVID-19. However, there were not enough studies involving pregnant women with severe COVID-19, especially in Korea. The purpose of this study was to analyze the cases of pregnant women with COVID-19 infection with various severities, and to compare and describe the clinical course and the effects on pregnancy and perinatal prognosis according to severity.

#### **Materials and Methods**

We retrospectively analyzed the medical records of adults 18 years of age or older who were hospitalized in the Gachon University Gil Medical Center with PCR-confirmed COVID-19 and proved pregnancy, from February 1, 2020 to January 31, 2022. Through the epidemiological investigation report, the patient's medical history, obstetric history, date of diagnosis and variants of COVID-19, and vaccination history were collected. Clinical symptoms, oxygen demand, chest imaging, treatment, perinatal complications, fetal conditions, delivery results, and complications were collected through medical records.

#### Results

A total of 104 pregnant women with PCR-confirmed COVID-19 were hospitalized. The age at the time of diagnosis was 33  $\pm$ 4.24 (Mean  $\pm$  SD) years, and 4 patients (3.8%) were vaccinated with the COVID-19 vaccine. During hospital stay, the most common complaints were cough (99 patients, 95.2%) and fever (85 patients, 81.7%). Oxygen was applied in 40 patients (38.5%), and in 19 patients (18.3%) in severe cases. Thirty-seven patients (35.6%) delivered during isolation treatment. Critical COVID-19 patients' group has statistically significant higher rate of preterm delivery compared with mild COVID-19 patient group (31.6 % versus 6.3 %, p=0.009). One patient died from septic shock caused by multidrug-resistant *Acinetobacter baumannii* during treatment. A total of 39 babies were born, of which 4 received postnatal oxygen therapy.

## Conclusion

Pregnant women with COVID-19 had higher mortality rates, aggravation rates, and premature birth rates compared to nonpregnant patients of the same age. In a situation where effective and safe COVID-19 treatments for pregnant women are limited, it is necessary to increase the vaccination rate to prevent undesired outcomes in both mother and child.

	Disease severity			_	
Gestational age at delivery	Mild (n=22)	Moderate (n=12)	Severe (n=8)	Total (n=42)	
Full term (≥ 39 weeks)	8 (19%)	2 (5%)	0 (0%)	10 (24%)	<ul> <li>Table 1.</li> <li>Perinatal outcomes according to COVID-19 severity</li> </ul>
Early term (37+0 to 38+6 weeks)	10 (24%)	6 (14%)	2 (5%)	18 (43%)	
Late preterm (34+0 to 36+6 weeks)	2 (5%)	3 (7%)	4 (10%)	9 (21%)	
Early preterm (< 34 weeks)	2 (5%)	1 (2%)	2 (5%)	5 (12%)	<sup>a</sup> P=0.007 for the overall outcomes
All <sup>a</sup>	22 (52%)	12 (29%)	8 (19%)	42 (100%)
