

Cleveland Clinic CROHN'S DISEASE PATIENTS TREATED WITH ANTI-TNFS HAVE LOWER RATES OF MYOCARDITIS

Khaled Alsabbagh Alchirazi MD, Abdul Mohammed MD, Ahmed Eltelbany MD MPH, Osama Hamid MD, Miguel Regueiro MD. Cleveland Clinic Foundation

Introduction

- Myocarditis is a rare extraintestinal cardiac manifestation of IBD
- It is more commonly reported in Ulcerative Colitis than in Crohn's disease (CD) and consequently not frequently reported.
- The prevalence of myocarditis in CD patients on immunosuppressive and immunomodulatory therapy is not well known.

Aim

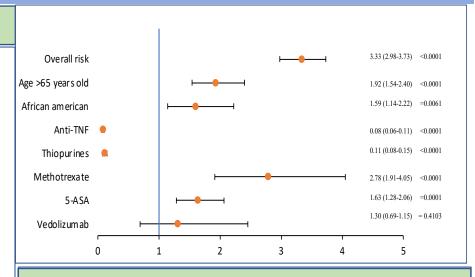

Our study aims to assess the prevalence of myocarditis and the effect of immune-modifying therapy in CD.

Methods

- **Explorys Database**
- Retrospective cohort 1999-2022
- Patients >18 years old
- Investigated the prevalence of myocarditis in CD patients.
- Compared the prevalence between CD patients with and without immune- modifiying agents.

Results

Of the 70, 301,380 individuals in the database from 1999 to present, we identified 249,300 (0.3%) patients with CD, of whom 40,840 (16.4%) patients received anti-TNFs. CD patients were 59.4% females, 76% Caucasian, and 70% in 18-65 years age group. The prevalence of myocarditis was 0.12% for CD compared to 0.04% in individuals without IBD, p< 0.001. Compared to the general population, patients with CD had higher association risk of myocarditis diagnosis [OR: 3.33, p< 0.0001]. Among CD, predictors of having myocarditis included being elderly (>65 y/o), African American, smokers and has history of type 2 diabetes (P< 0.0001). The prevalence of myocarditis was significantly lower CD patients on anti-TNF agents [OR: 0.08, p < 0.0001], and thiopurines [OR: 0.11, p < 0.0001] whereas methotrexate and 5aminosalicylates (5-ASA) had higher rates [OR: 2.78, p < 0.0001] and [OR: 1.63, p =0.0001], respectively. No significant effect was noted with Vedolizumab [OR: 1.30, P= 0.4103] (figure 1).

Discussion

We found a higher risk association between CD and myocarditis. Anti-TNF agents and thiopurines were less likely to be associated with myocarditis, while methotrexate and 5-ASA were more likely to be associated with myocarditis in CD. The difference in the association between immune-modifying agents is unclear. Hence, further prospective studies are required to evaluate this association. Our findings may have significant implications for patients with cardiac risk factors and underlying myocardial dysfunction.
