Endoscopic Sleeve Gastroplasty in Class III Obesity (BMI>40): A Propensity-Matched, **Retrospective Comparison of Short-Term Safety and Efficacy vs Bariatric Surgery**

ABSTRACT

Background: Endoscopic sleeve gastroplasty (ESG) is still mainly proposed for patients with BMI 30-40, although there are no guidelines specifying applicability. There is little data comparing ESG to bariatric surgery in patients with class III obesity (BMI > 40).

Aim: To assess short-term safety and efficacy of ESG and compare it to sleeve gastrectomy (SG) and gastric bypass (RNYGB), in patients with class III obesity.

Methods: We retrospectively analyzed over 500,000 patients with BMI>40 undergoing ESG, SG, and RNYGB in the Metabolic and Bariatric Surgery Accreditation and Quality Improvement Program database from 2016-2020. ESG patients were stratified by BMI to compare outcomes between Class III versus Class I-II obesity. Class III obese patients undergoing ESG were also propensity matched to SG and RNYGB cohorts for an adjusted comparison. Primary outcomes included adverse events (AE), readmissions, re-operations, and re-interventions within 30days after procedure. Secondary outcomes included procedure time, length of stay (LOS), and early weight loss.

Results: Of patients undergoing ESG, there was no difference in AE, readmissions, or reinterventions between Class III obesity and Class I-II obesity (p>0.05), while Class III obese patients achieved greater %TBWL at 30d (p<0.05). For class III obese patients, ESG had comparable AE to SG and less than RNYGB. ESG achieved similar %TBWL as SG and RNYGB within 30d.

Conclusions: This is the largest study yet evaluating ESG in class III obesity. ESG is safe in this population, with no difference in AE between obesity classes. The safety and efficacy of ESG mirrored SG and was safer than RNYGB.

✓ When compared to bariatric surgery, ESG had a **comparable rate of AE to SG** and significantly fewer AE than RNYGB, while achieving similar **short-term weight loss** in patients with BMI>40.

 Further studies evaluating long-term durability and cost-effectiveness of ESG in class III obesity are warranted.

WAHealth

DISCUSSION & CONCLUSION

nong patients undergoing ESG, patients with >40 had **no difference** in AE, readmissions, terventions, or re-operations, compared to those BMI 30-40

Clinicians should consider expanding access to ESG for patients regardless of BMI class.
