Neuroleptic Malignant Syndrome from Oxcarbazepine & Topiramate Withdrawal: A Case Report

Son Dang MD Normeen Siddiqui BS Sachidanand Peteru MD Grace Vallejo MD Mohammad Raja MD Arsen Askandaryan MD

Consultation & Liaison Service Department of Psychiatry Jamaica Hospital Medical Center Jamaica, NY 11418

> Neuroleptic malignant syndrome is a dose-independent idiosyncratic reaction from dopamine modulating pharmacologic agents.

 \geq Incidence rate between 0.02% to 3% from various regional studies.

 \geq Mortality rates ranges from 7% to 15%.¹ Often associated with first gen. antipsychotic medications.

> We describe a unique NMS case that lack the use of antipsychotic and direct dopamine modulators.

> PMHx: Autism spectrum disorder, disruptive mood dysregulation disorder, generalized anxiety disorder, spastic cerebral palsy, obesity. \geq Psychotropic regimen: Oxcarbazepine 600mg BID for off-labeled DMDD, topiramate 200mg qHS for weight-loss and insomnia, lorazepam 1mg TID, and clonidine 0.2mg BID for anxiety. baseline, he is talkative & confirmed medication compliance but had stopped in the past week due to poor oral feeding. \rightarrow admitted for failure to thrive & secondary acute kidney injury on preliminary lab work-up.

 \geq 20yo male presented with altered mental status & poor oral feeding. \succ ED evaluation was limited due to patient being "mute". Family states at \succ In the ED, pt. was hemodynamically unstable \rightarrow NS fluid resuscitation

activation of sepsis protocol & further lab workup (table 1). verbal /w bilateral upper extremities stiffness \rightarrow recommended for IM/IV

 \succ On admission, pt. spiked a fever of 102.7F /w persistent tachycardia \rightarrow Simultaneously, C&L consulted for behavioral agitation. Pt noted to nonlorazepam & hold all psych meds amid suspicions for NMS.

 \succ ID consultation \rightarrow lumbar puncture \rightarrow empiric ceftriaxone, acyclovir, vancomycin & dexamethasone. Despite fluids & NSAIDs, his fever was unwavering /w rising interval CPK \rightarrow ICU upgrade.

> EEG r/o seizure activities. CT head, chest, & abd/pelvis showed no acute abnormality. CSF analysis r/o infectious meningoencephalitis & discontinued empiric coverage. Anesthesia consultation \rightarrow unlikely malignant hyperthermia due to lack of exposure to inhaled anesthetics & neuromuscular paralytics.

 \succ NMS criteria fulfilled as diagnosis of exclusion \rightarrow C&L recommend for dantrolene 150mg TID x3 days & amantadine 100mg BID \rightarrow clinical & interval lab improvements. Despite being on prophylactic SQ heparin, his recovery was complicated by worsening dyspnea & tachycardia \rightarrow CTPA /w bilateral submassive PE (figure 1) \rightarrow therapeutic LMWH. > Repletion of dopamine agonist was tapered & LMWH was transition to oral apixaban. Pt was discharged w/o recurrence of NMS to date.

There are bilateral consolidations in the left and right lower lobes (bl by contrast filling defects (re - 1B) Right heart strain demonstrated by dilatation of pulmonary trunk to 2.99 cm (yellow line)

> This case emphasizes the need for having a high suspicion of NMS, even in the absence of antipsychotics, and when it is masked by concurrent medical conditions.²

DISCUSSION

 \geq Figure 2 represents the identified causes of NMS reported by the FDA adverse event system from 1968-2021.

> Figure 3 describes the basal ganglia regulatory function on motor movements. Disruption in dopamine for D1&D2 receptors \rightarrow muscle rigidity.

>Currently there are no literature recognizing oxcarbazepine & topiramate withdrawal as causation for NMS. >However, these medications are well-recognized in promoting & indirectly increasing the release of dopamine within the CNS.³⁻⁵ >Physicians should be aware of possible triggers of NMS & preventatively warned pts. from abrupt antiepileptics discontinuation.

 \succ Additionally, it reiterates the need for early & aggressive treatment to prevent further morbidity and complications.

e 2. Pharmacologic Agents Most Commonly Associated with NMS from FAERS (From 1968 to June 30, 2021)

3. Normal Basal Ganglia Motor Regulatory Functions

Direct Pathway

- 1) Cortex \rightarrow SNpc (Releases dopamine to striatum)
- 2) \rightarrow Striatum (Activated DI receptors, releases GABA to GPi)
- (No release of GABA to Thalamus)
- (release Glutamate to Cortex)
- 5) \rightarrow Activated Primary Motor Cortex

Indirect Pathway

- Cortex \rightarrow SNpc (Releases dopamine to striatum)
- \rightarrow Striatum (Activated D2 receptors inhibits GABA release to GPe)
- \rightarrow Uninhibited GPe (releases GABA to STN)
- (No release of Glutamate to GPi)
- (No release of GABA to Thalamus)
- (release Glutamate to Cortex)
- 7) \rightarrow Activated Primary Motor Cortex
